Session 11:

Machine learning introduction

Andreas Bjerre-Nielsen

Agenda

- 1. Why machine learing
- 2. What is machine learning
- 3. Classification models
 - A. the perceptron
 - B. beyond the perceptron
 - C. maximum margin classification

Why machine learning

Value of modelling (1)

Why are models useful?

Models are pursued with differens aims.

- Social science:
 - They teach us something about the world.
- Data science:
 - To make decisions.
 - They can extract useful information.
 - Make pre

Value of modelling (2)

How can we express these goals in terms of modelling?

Suppose we have a regression model, $y=X\beta+\epsilon$. What are the agendas?

- Social science: parameter estimates, i.e. $\hat{\beta}$.
- Data science: prediction of output, i.e. \hat{y} .
 - Note parts of social science, e.g. finance and demography, are quite interested in prediction too.

Model fragility (1)

What is a taylor approximation?

- Fitting a curve with an *n-dimenstional polynomial*
- Can fit any "regular" curve

Model fragility (2)

What is one of the essentiale problems in prediction?

• What data and what model to use.

Suppose we have all the data in the world. We estimate a model. What tradeoff do we face?

- •
- •

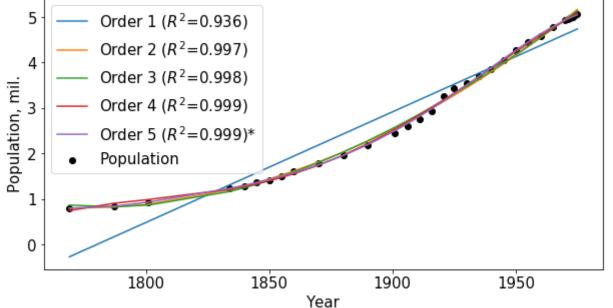

Model fragility (3)

Suppose we build models of the size of the Danish population, how do polynomial fits perform?

• We use data from the years 1769-1975.

In [13]: f_pop1
Out[13]:

5 Order 1 (R²=0.936)

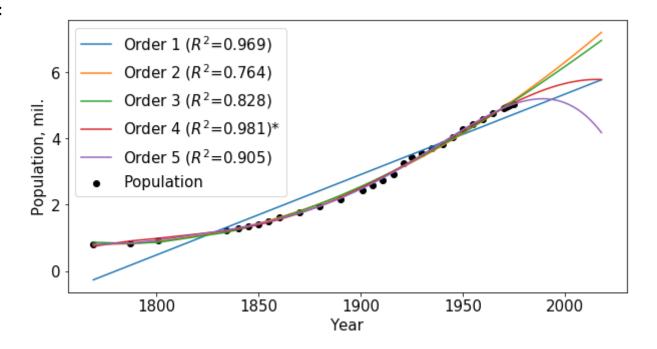

Model fragility (4)

Which model performs best when we extend the period to 1975?

In [14]: f_pop2

Out[14]:

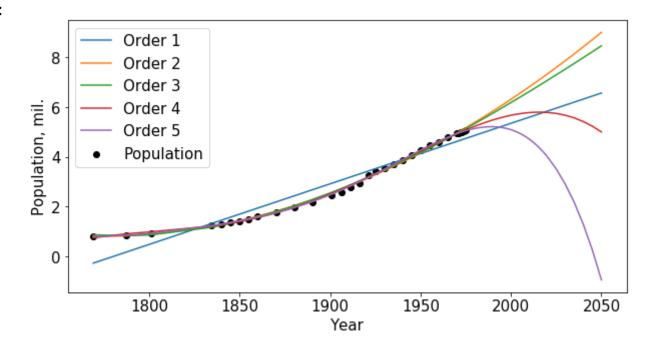

Model fragility (5)

What happens if we extend the prediction period until 2050?

In [15]: f_pop3

Out[15]:

Model fragility (6)

What trade off do we face in modelling?

- Making a model that is to simple and does not capture enough of data (underfitting)
- Making a model with great fit on estimation data, but poor out-of-sample prediction (overfitting)

The goal of machine learning is to find models that minimize these problems.

Machine learning overview

What is machine learning (1)

Can you define machine learning, i.e. ML?

- Supervised learning
 - Models designed to infer a relationship between input and labeled data.
 - Requirement: labels on data
- Unsupervised learning
 - Find patterns and relationships from **unlabeled** data.
 - This may involve clustering, dimensionality reduction and more.

What is machine learning (2)

How might this be useful for social scientists?

- Supervised:
 - •
 - •
- Unsupervised:
 - •

What is machine learning (3)

How can we categorize a supervised learning models?

Suppose we have model

$$y=w_0+w_1x_1+\ldots+w_kx_k$$

• We distinguish by type of the target variable y

What is machine learning (4)

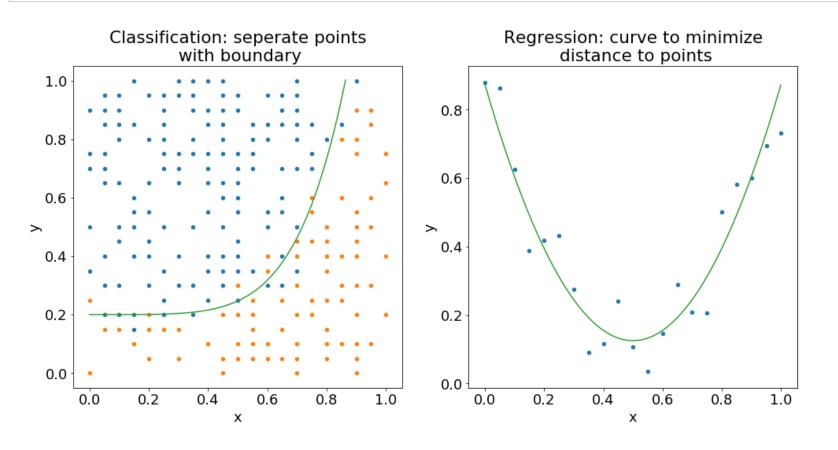

Which one is classification, which one is regression?

In [16]: f_identify_question Out[16]: Draw a boundary that separate Draw a line that minimizes the the point clouds distance to the points 1.0 0.8 0.8 0.6 0.6 \geq 0.4 0.4 0.2 0.2 0.0 0.0 0.2 0.2 0.8 0.8 0.0 0.4 0.6 1.0 0.0 0.4 0.6 1.0 Х Х

What is machine learning (5)

In [17]: f_identify_answer

Out[17]:

Regression models

What are examples of regressions models?

•

What is the underlying data of the target, y?

• target is continuous

Classications models

What are examples of classication models?

What is the underlying data of the target, y?

- target is categorical
 - sometimes known asfactor
 - can also be bool or int

The perceptron model

The articifial neuron

We are interested in making a decision rule $\phi: \mathbb{R}^{\Bbbk} o \{-1,1\}$.

$$\phi(z_i) = \left\{egin{array}{ll} 1, & z_i > 0 \ -1, & z_i \leq 0 \end{array}
ight.$$

$$ullet$$
 net-input, $z_i = \underbrace{oldsymbol{w}^Toldsymbol{x}_i}_{vector\ form} = \underbrace{w_0 + w_1x_{i,1} + \ldots + w_kx_{i,k}}_{expanded\ form}$

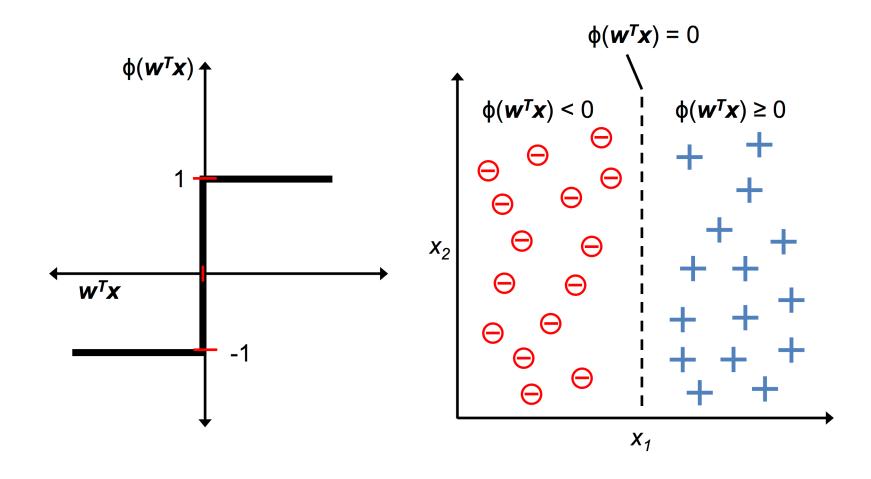

- feature vector, \mathbf{x}_i , i.e a row of input variables
 - ~ explanatory variables in econometrics
- weight vector, **w**, i.e model parameters
 - lacktriangle ~ coefficients in econometrics where denoted eta
- ullet unit step function, ϕ , checks if value exceeds threshold
- bias term, w_0 , i.e. the model intercept
 - \sim the constant variable in denoted eta_0

The articifial neuron (2)

Quiz: what are the input dimensions of the neuron, what is the output dimension?

- Input is the n-dimensional space, \mathbb{R}^2 .
- Output is binary, either -1 or 1.

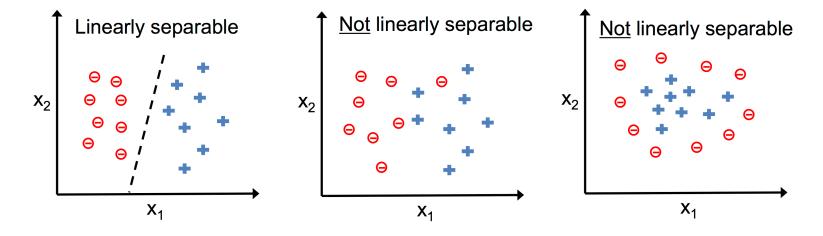

The articifial neuron (3)

The articifial neuron (4)

When does the articial neuron work?

If the two target types are linearly separable:

The perceptron learning rule (1)

How do we estimate the model parameters?

- 1. initialize the weight with small random number
- 2. for each training observation, i=1,..,n
 - A. compute predicted target, \hat{y}_i
 - B. update weights \hat{w}

The perceptron learning rule (2)

How do we build the model?

- 1. initialize the weight with small random number
- 2. for each training observation
 - A. compute predicted target, \hat{y}
 - B. update weights \hat{w}

The perceptron learning rule (3)

How do we predict the target?

Single observation:

$$egin{aligned} \hat{y}_i = & \phi(z_i), \quad z_i = w_0 + w_1 x_{i,1} + \ldots + w_k x_{i,k}, & ext{expanded notation} \ \hat{y}_i = & \phi(z_i), \quad z_i = \hat{oldsymbol{w}}^T oldsymbol{x}_i, & ext{vector notation} \end{aligned}$$

Multiple observations

$$\hat{m{y}} = \phi(m{z}), \quad m{z} = m{X}\hat{m{w}}, \qquad ext{matrix notation}$$

The perceptron learning rule (4)

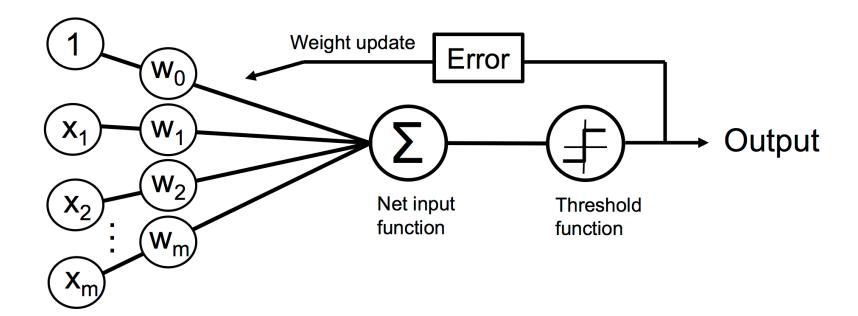

How do we update weights?

Weights are updated as follows:

$$egin{aligned} \hat{w} &= \hat{w} + \Delta \hat{w} \cdot \eta \ \Delta \hat{w} &= (y_i - \phi(z_i)) \cdot \mathbf{x}_i \end{aligned}$$

The perceptron learning rule (5)

The computation process

Implementation in Python (1)

How do we compute the errors?

```
In [18]: X = np.random.normal(size=(3,2))
y = np.array([1,-1,1])
w = np.random.normal(size=(3))

z = w[0]+X.dot(w[1:])

e = y-np.where(z>0, 1, -1)
SSE = e.T.dot(e)
```

Implementation in Python (2)

How do we compute the updated weights?

```
In [19]: eta = 0.001 # Learning rate
fod = X.T.dot(e)
    update_vars = eta*fod
    update_bias = eta*e.sum()
```

Working with the perceptron (1)

We load the iris data

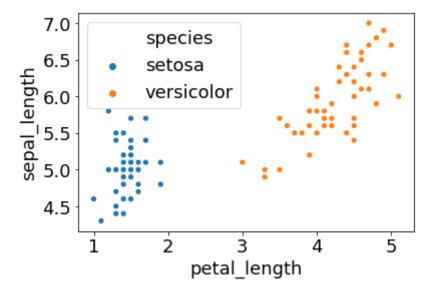

- drop virginica species
- only use sepal_length and sepal_width

```
In [20]: iris = sns.load_dataset('iris').iloc[:100] # drop virginica

X = iris.iloc[:, [0, 2]].values
y = iris.species.map({'setosa':1, 'versicolor':-1}).values
```

In [21]: sns.scatterplot(iris.petal_length, iris.sepal_length,hue=iris.species)

Out[21]: <matplotlib.axes._subplots.AxesSubplot at 0x299ae675dd8>

Working with the perceptron (2)

How do we fit the perceptron model? perceptron definition

```
In [22]: # initialize the perceptron
    clf = Perceptron(n_iter=10)

# fit the perceptron
    # runs 10 iterations of updating the model
    clf.fit(X, y)
```

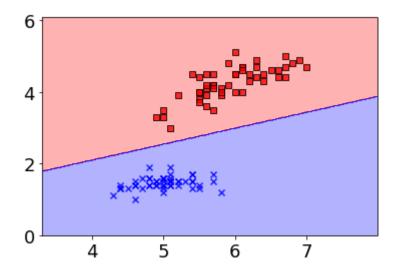

Out[22]: <ch02.Perceptron at 0x299afab26a0>

Working with the perceptron (3)

How can we evaluate the model??

```
In [24]: print('Number of errors: %i' % sum(clf.predict(X)!=y))
    # we plot the decisions
    plot_decision_regions(X,y,clf)
```

Number of errors: 0

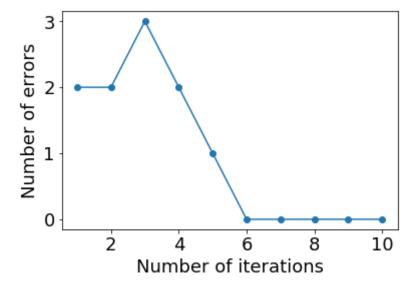

Working with the perceptron (4)

How does the model performance change??

```
In [25]: plt.plot(range(1, len(clf.errors_) + 1), clf.errors_, marker='o')
    plt.xlabel('Number of iterations')
    plt.ylabel('Number of errors')
```

Out[25]: Text(0,0.5,'Number of errors')

Beyond the perceptron

Motivation

What might we change about the perceptron?

- 1. Change from updating errors that are binary to continuous
- 2. Use more than one observation a time for updating

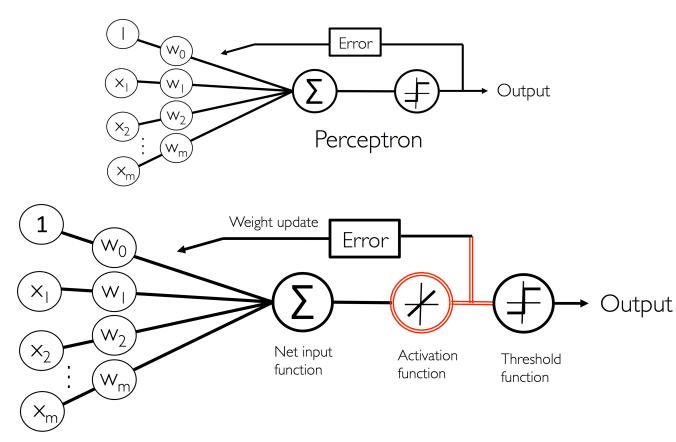

The activation function (1)

What else might we use to update errors?

• The most simple is **no transformation** of the net-input, i.e. $\phi(z_i)=z_i$.

The activation function (2)

How is this different from the Perceptron?

Adaptive Linear Neuron (Adaline)

The activation function (3)

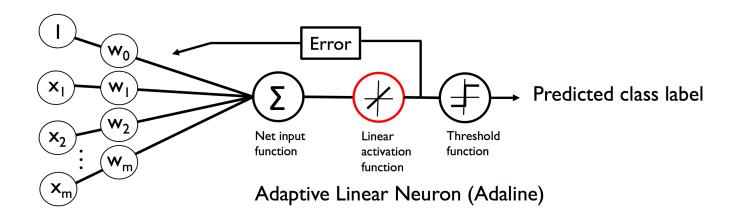

Which activation functions can be used?

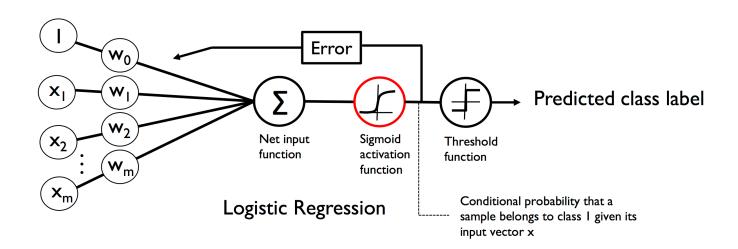

- Linear
- Logistic (Sigmoid)
- Unit step, sign

See page 450 in Raschka and Mirjalili.

The activation function (4)

How do Adaline and Logistic regression differ?

A new objective (1)

The update rule in perceptron seems ad hoc, is there a more general way?

• Yes, we minimize the sum of squared errors (SSE). The SSE for Adaline is:

$$SSE = e^T e$$

 $e = y - Xw$

Doesn't the above look strangely familiar?

- Yes, it is the same objective as OLS.
- But no, we will not solve like OLS.

A new objective (2)

So how the hell do we solve the model?

- We approximate the solution. Two options:
 - We approximate the first order derivative ~ gradient descent (GD)
 - We approximate both first and second order derivative ~ quasi Newton
- We take gradient descent much simpler (sometimes faster)

A new objective (3)

What is the first order derivative of SSE in Adaline?

$$rac{\partial SSE}{\partial \hat{w}} = \mathbf{X}^T \mathbf{e},$$

How do we update with GD in Adaline?

• Idea: take small steps to approximate the solution.

$$oldsymbol{\Phi} oldsymbol{\Delta} \hat{w} = \eta \cdot \mathbf{X}^T \mathbf{e} = \eta \cdot \mathbf{X}^T (\mathbf{y} - \hat{\mathbf{y}})$$

A new objective (4)

The gradient descent algorithm we just learned uses the whole data.

• Often known as batch gradient descent.

What might be a smart way of changing (batch) gradient descent?

- we only use a subset of the data
- this called stochastic gradient descent (SGD)

Working with the logistic regression (1)

We load the titanic data and split into test and training sample

```
In [26]: cols = ['survived','class', 'sex', 'sibsp', 'age', 'alone']
    titanic = sns.load_dataset('titanic')
    titanic_sub = pd.get_dummies(titanic[cols].dropna(), drop_first=True).astype(np.int64)

print(titanic_sub.head(2))

X = titanic_sub.drop('survived', axis=1)
y = titanic_sub.survived
```

```
        survived
        sibsp
        age
        alone
        class_Second
        class_Third
        sex_male

        0
        0
        1
        22
        0
        0
        1
        1

        1
        1
        1
        38
        0
        0
        0
        0
        0
```

Working with the logistic regression (2)

```
In [27]: from sklearn.model_selection import train_test_split
    from sklearn.linear_model import LogisticRegression

# we split data
X_train, X_test, y_train, y_test = train_test_split(X, y, test_size=.5, random_state=0)

# estimate model on train data, evaluate on test data
clf = LogisticRegression()
clf.fit(X_train, y_train) # model training
accuracy = (clf.predict(X_test)==y_test).mean() # model testing
print('Model accuracy is:', np.round(accuracy,3))
```

Model accuracy is: 0.79

Maximum margin classification

Motivation

Does the perceptron care for how linear separation is done?

• No, as long as it classifies correctly then it is indifferent

Why is this a problem?

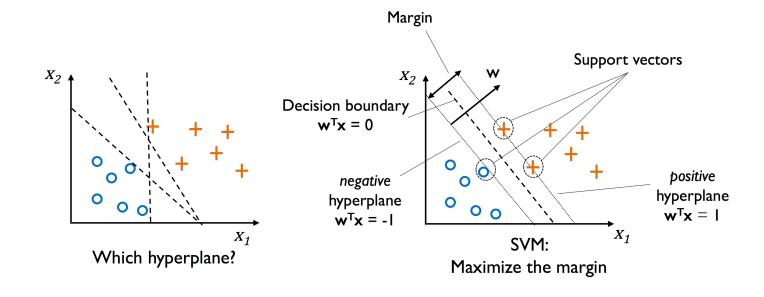

• It makes the model perform worse out-of-sample.

Maximum margin classification

How might we improve the sepearation?

We use a Support Vector Machine (SVM) we get a solution.

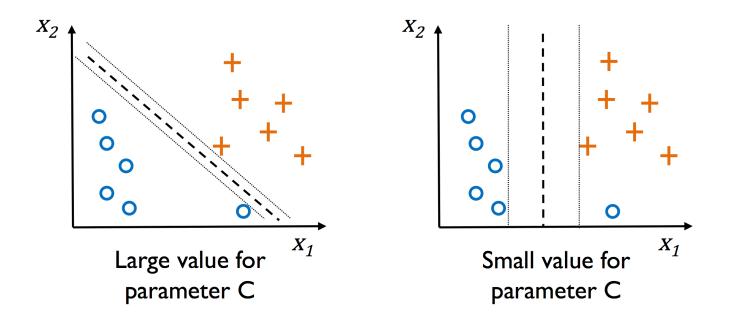

SVM finds a decision boundary which maximize distance to nearest points:

Support vector machines

How might we improve SVM?

• We can use soft-margin classification. This extends the distance to boundary by ignoring a number of miss-classifications, likely outliers.

• SVM can also handle non-linearities using kernel methods.

The end
